Bipolar transistors are so named because the controlled current must go through two types of semiconductor material: P and N. The current consists of both electron and hole flow, in different parts of the transistor. Bipolar transistors consist of either a P-N-P or an N-P-N semiconductor "sandwich" structure.

• The two junctions are termed the base-emitter junction and the base-collector junction • The term bipolar refers to the use of both holes and electrons as charge carriers in the transistor structure • In order for the transistor to operate properly, the two junctions must have the correct dc bias voltages – the base-emitter (BE) junction is forward biased($\approx 0.7V$ for Si, $\approx 0.3V$ for Ge) – the base-collector (BC) junction is reverse biased Architecture of a BJTs
