Indirect Posterior Restoration: Composite Inlays
Composite inlays and onlays can be placed to reduce polymerization shrinkage and composite wear. The advantage of this method is that the main part of the composite is cured outside the oral cavity and only a thin resin layer, the resin cement layer, contributes to shrinkage of the restoration in the oral cavity.

The curing occurs by subjecting the composite to heat, pressure or intense light, and this higher degree of cure improves strength and reduces wear; the indirect composite inlays/onlays are often referred to as ' super cured ' . This super curing does, however, leave fewer reactive resin groups to bond to the resin luting cement.

A systematic review and meta-analysis was performed to analyze the survival of onlay restorations in the posterior region, their clinical behavior according to the material used (ceramic reinforced with lithium disilicate, conventional feldspathic ceramic or reinforced with leucite; hybrid materials and composite), possible complications, and the factors influencing restoration success.

the onlay material used (beta = 0.064; p = 0.028). Composite onlays were associated with a lower survival rate over time. Onlays are a good, conservative, and predictable option for restoring dental defects in the posterior region, with a survival rate of over 90%. The survival rate decreases over time and with the use of composite as onlay material.

Composite Inlays and Onlays are unique dental restoration processes used to repair damaged teeth and prevent further tooth decay. Although similar, they each serve a particular role in restoring teeth to natural, healthy forms. Inlays are used when the decay or damage is within the indented top surface (cusp) of a tooth.
