There are several approaches for graph drawing, which differ considerably by their methodology. We shall present two of them here: spring embedding and straight line embedding. LEDA offers these and other good algorithms for drawing graphs via functions declared in the header file graph\_draw.h.

The Reingold-Tilford tree-drawing algorithm draws ordered trees (that is, trees where the edges from a vertex are ordered). Your examples suggest that your graphs are not ordered, and indeed that the main issue you face is finding an edge-ordering which minimizes edge-crossing. So possibly this is the problem you are looking to solve.

Layered graph drawing algorithms - also known as hierarchical layout or Sugiyama algorithm - distribute the nodes over layers so that most of the edges point in the main layout direction. This arrangement facilitates the identification of dependencies and hierarchic relationships between the elements in the graph.

### Automatic Graph Drawing

The crossing number of a drawing is the number of pairs of edges that cross each other. If the graph is planar, then it is often convenient to draw it without any edge intersections; that is, in this case, a graph drawing represents a graph embedding.However, nonplanar graphs frequently arise in applications, so graph drawing algorithms must generally allow for edge crossings.

Abstract: Do algorithms for drawing graphs pass the Turing Test? That is, are their outputs indistinguishable from graphs drawn by humans? We address this question through a human-centred experiment, focusing on 'small' graphs, of a size for which it would be reasonable for someone to choose to draw the graph manually.

### The Turing Test for Graph Drawing Algorithms

Another algorithm that we can use to change the layout of any graph into an orthogonal graph is the so-called bend minimization algorithm. We first start with any planar graph: Then, we convert it to its high visibility form, which consists in the transformation of the vertices into parallel horizontal lines:

Force-directed graph drawing algorithms are a class of algorithms for drawing graphs in an aesthetically-pleasing way. Their purpose is to position the nodes of a graph in two-dimensional or three-dimensional space so that all the edges are of more or less equal length and there are as few crossing edges as possible, by assigning forces among the set of edges and the set of nodes, based on their relative positions, and then using these forces either to simulate the motion of the edges and nodes

Git Cola's algorithm has the particularity of placing several commits on the same row. The others draw the commit graph next to the commit history and thus they draw only one commit per row. Gitk draws a graph very similar to the one printed by the command git log --graph.
