In the Heston model, arguably the most popular model of stochastic volatility, the fair variance of a variance swap and the fair volatility of a volatility swap may be computed analytically. In this two-factor model, both the price and the variance are

Variance and Volatility Swaps in the Heston Model

Under the Heston model, the total (or cumulated) variance $V_t = \int_0^t \sigma^2 ds$ follows an integrated CIR process and has thus $V_t(u) := E[\exp(iuV_t)] = \exp(2t \int_0^1 \exp(2v \sigma^2 u) + \coth(t=2) \cosh(t=2) + 1 \sinh(t=2) \sigma^2 = 2; \text{ where } \rho = \rho \sigma^2 2iu$ as characteristic function (see [10]). The expected annualized variance for the time horizon T is thus given by $\int_0^T E[V_t] dt := \int_0^T \sigma^2 dt = \sigma^2 T$

Heston Model: the Variance Swap Calibration

From Wikipedia, the free encyclopedia In finance, the Heston model, named after Steven Heston, is a mathematical model describing the evolution of the volatility of an underlying asset. It is a stochastic volatility model: such a model assumes that the volatility of the asset is not constant, nor even deterministic, but follows a random process.

Abstract This paper features a market implied methodology to infer adequate starting values for the spot and long-run variances and for the mean reversion rate of a calibration exercise under the Heston model.

Abstract This paper features a market implied methodology to infer adequate starting values for the spot and long run variances and for the mean reversion rate of a calibration exercise under the Heston model.

Heston Model: The Variance Swap Calibration by Florence ...

In the Heston model, arguably the most popular model of stochastic volatility, closed-form solutions exist for the prices of various contingent claims on realized variance and volatility. For example, analytical formulae can be derived for the fair variance of vanilla, capped, conditional and corridor variance swaps, the fair volatility of a volatility swap, and the fair value of European options on realized variance.

Variance and Volatility Derivatives in the Heston Model ...

The Heston model is an industry standard model which can account for the volatility smile seen in the market. The FINCAD Analytics Suite functions introduced in 2008 allow fast pricing of European options, variance and volatility swaps, necessary for calibration routines; the calibration itself; calculation of the Greeks, including sensitivities to the Heston model parameters; and calculation of the implied volatility surface for a given set of such parameters.

The Heston Model of Stochastic Volatility: Fast Option ...

The formula for pricing variance swaps with Heston is much simpler than the formula for the replication strategy. However, since calibration can be quite demanding, the overall complexity is more or less the same. This research can be extended further to pricing variance swaps with caps and floors, corridor and conditional variance swaps.

Pricing variance swaps by using two methods: replication ...

The five Heston model parameters are: the initial variance V_0 , the long-term variance V_∞ , the speed of mean reversion K , the volatility of volatility η , and the correlation ρ . For the valuation of a variance swap, the expected total variance $E[V_T]$ over the term of the swap has to be calculated.

Valuation of Variance and Volatility Swaps | FINCAD

a volatility or variance swap is equal to the realized volatility or variance over a pre-specified period minus a pre-set delivery price of the contract multiplied by a notional amount of the swap in dollars per annualized volatility point.

A Closed-form Exact Solution for Pricing Variance Swaps ...

The discrete sample time generalized realized variance (gRV) of the variance swap under log returns is $gRV = \sum_{j=1}^M w_j \log S(t_j) - \log S(t_0) - \frac{1}{2} \sum_{j=1}^M w_j \sigma^2$, where $0 = t_0 < t_1 < t_2 < \dots < t_M = T$, T is maturity time, M is the sampling frequency, $S(t)$ is the asset price at time t following the hybrid Heston–CIR model in a finite time interval $[0, T]$ and w_j denotes a discrete weight process given by the form of volatility exposure.

This paper features a market implied methodology to infer adequate starting values for the spot and long-run variances and for the mean reversion rate of a calibration exercise under the Heston model. More particularly, these initial parameters are obtained by matching the term structure of the future expected total variance, inferred from the volatility surface, with the model term structure.

The purpose of introducing jumps in returns and variance dynamics is to make the Heston model consistent with short-term variance swaps with cap protection for which market prices are typically lower than theoretical prices implied by the Heston 2 model with no jumps.

Pricing Options on Realized Variance in Heston Model with ...

Any volatility smile model which prices vanilla options can therefore be used to price the variance swap. For example, using the Heston model, a closed-form solution can be derived for the fair variance swap rate. Care must be taken with the behaviour of the smile model in the wings as this can have a disproportionate effect on the price.

We develop analytical methodology for pricing and hedging options on the realized variance under the Heston stochastic variance model (1993) augmented with jumps in asset returns and variance.

Abstract. In this paper, we propose a two-factor Heston–CIR hybrid model for the pricing of variance and volatility swaps, by introducing the second regime switching factor into the Heston–CIR hybrid model. While this model is closer to reality, taking advantages of the Heston stochastic volatility, CIR stochastic interest rate and regime switching, it has a more complicated structure and thus leads to extra difficulty in finding analytical solutions.

We first extend the framework of by incorporating the CIR interest rate into their Heston model for pricing discretely-sampled variance swaps. We impose partial correlation between the asset price and the volatility, and derive a semi- closed form pricing formula for the fair delivery price of a variance swap.
