Margins Manual Stata

A margin is a statistic based on a fitted model in which some of or all the. margins— Marginal means, predictive margins, and marginal effects 9. covariates are fixed. Marginal effects are changes in the response for change in a covariate, which can be reported as a derivative, elasticity, or semielasticity.

Interpret ...

Margins are statistics calculated from predictions of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates. The margins command estimates margins of responses for specified values of covariates and presents the results as a table.

Description Quick start - Stata: Software for Statistics ...

The first margin, 0.13, is the average probability of a positive outcome, treating

everyone as if they were male. The second margin, 0.19, is the average probability of a positive outcome, treating everyone as if they were female. We can compare females with males by rerunning margins and adding a contrast operator:

Title stata.com margins, contrast – Contrasts of margins

The margins command can very easily tell you the mean effect: margins, dydx(weight) What margins does here is take the numerical derivative of the expected price with respect to weight for each car, and then calculates

the mean. In doing so, margins looks at the actual data. Thus it considers the effect of changing the Honda Civic's weight from 1,760 pounds as well as changing the Lincoln Continental's from 4,840 (the weight squared term is more important with the latter than the former).

Exploring Regression Results using Margins

the margins and the x axis represents one or more factors or continuous covariates.

Specifying horizontal swaps the axes so that the x axis represents the estimates of the margins.

Using Margins for Predicted Probabilities. The margins command (introduced in Stata 11) is very versatile with numerous options. This page provides information on using the margins command to obtain predicted probabilities. Let's get some data and run either a logit model or a probit model. It doesn't really matter since we can use the same margins commands for either type of model.

Using Margins for Predicted Probabilities

argins computes so-called margins of responses. `IA \margin` is a statistic computed from predictions from a model while manipulating the values of the covariates. `F\conditional margin`: a prediction from a model where all covariates are set to xed values. `F\predictive margin`: if some covariates are not xed.

contrasts ...

Stata 11 introduced new tools for making such calculations—factor variables and the margins command. These can do most of the things that were previously done by Stata's own adjust and mfx commands, and much more.

Unfortunately, the complexity of the margins syntax, the daunting 50-page reference manual entry that describes it,
