A parametric method would involve the

calculation of a margin of error with a formula, and the estimation of the population mean with a sample mean. A nonparametric method to calculate a confidence mean would involve the use of bootstrapping.

Nonparametric statistics is the branch of statistics that is not based solely on parametrized families of probability distributions (common examples of parameters are the mean and variance). Nonparametric statistics is based on either being distribution-free or having a specified distribution but with the distribution's parameters unspecified. Nonparametric statistics includes both descriptive statistics and statistical inference.

Nonparametric statistical methods are used for drawing inferences about a population based on a sample. They make fewer assumptions about the nature of the population than do the parametric techniques usually taught in an introductory statistics course.

Nonparametric methods are procedures of statistical inference for models without precise assumptions about the distribution of the sample. A typical case is the two-sample test problem, where samples from two populations are observed, and the hypothesis that two populations have the same distribution is tested.

This book links these two fields of modern statistics by explaining how functional data can be studied through parameter-free statistical ideas.
