In thermal power plants, the heat energy obtained from the combustion of fuel (coal/natural gas/other carbon base fuel) is used to convert water into steam. The high temperature and pressure steam are used to rotate the turbine blade, turbine shaft is connected to generator. The generator converts the kinetic energy into electric energy.

The water steam circuit of a thermal power generating plant is a semi-closed circuit. Here comparatively not much water is required to supply to the boiler from external sources since same water is reused again and again by condensing the steam after its mechanical work of rotating turbine. Here, water is first taken from a river or any other suitable natural source of water.

A generating station which converts heat energy of coal combustion into electrical energy is known as a steam power station.It can also be called as the thermal power station or thermal power generating plant. A steam power station basically works on the Rankine cycle.Steam is produced in the boiler by utilising the heat of coal combustion.

Steam Power Plant - Working Principle & Schematic Diagram
Most thermal power stations produce steam, and these are sometimes called steam power stations. Not all thermal energy can be transformed into mechanical power, according to the second law of thermodynamics. Therefore, heat loss to the environment is always there. If this loss is employed as useful heat, for industrial processes or district heating, the power plant is known as a cogeneration ...
