Transformer Short Circuit Current Calculation

The transformer short circuit current is calculated as follows:

$$I_{\text{fault-actual}} = \frac{S_{\text{base}} \times 100}{\sqrt{3} \times V_{\text{base}} \times Z_{\%}}$$

where $I_{\text{fault-actual}}$ is in kA,

(S_{base}) is in kVA, (V_{base}) is in V, and $(Z_{\%})$ is in percentage. This is basically a combination of the steps in the per-unit calculation method:

Calculate the short circuit current. We'll now calculate the actual short circuit current using the following formula. So, this is our Short circuit current. This will help you to decide the rating of circuit breaker. In this case you need a breaker who's fault current breaking capacity is more than 2624.1A or 2.6kA. You can also calculate primary current of any transformer in just 2 steps, to know more about it, [click here](#).

1.2 Needs of transformer short-circuit current calculation Today more than ever before, the electricity grid is developing so quickly — the power plant capacity, the substation capacity and electricity loads, as well as load density, sustainably grow. Take China as an example. The number of 500 kV substations in the

short circuit current of transformer, $I_{sc} = I_{sec} / Z = 131.2 / 0.05 = 2624.31$. $I_{sc} = 2.6\text{KA}$. in this way we can easily calculate the short circuit current of the any rated transformer. short circuit current rating almost 20 times greater than full load current of the transformer. so we need to choose the circuit breaker with breaking capacity of at least 2.7KA.

Now, we will calculate the value of the short circuit current on the secondary side of the transformer, it will help the protective device to act accordingly. $I_{sc} = ((100\%) / ((\text{Impedance of Transformer (Z\%)}))) * I_{sec}$ By plugging the values, we will get; $I_{sc} = (100 / 2.5) * 454.54$

Three Phase Transformer Full-Load Current (Amps) = $kVA \times 1000 / (1.732 \times V)$ Where: kVA = transformer rating (kilovolt-amperes), V = voltage (volts). Turns Ratio = $N_1 / N_2 = V_1 / V_2 = I_2 / I_1$. Where: N_1 = number of turns on the primary, N_2 = number of turns on the secondary, V_1 = primary voltage, V_2 = secondary voltage, I_1 = primary current, I_2 = secondary current.

A short circuit (S/C) in an electrical circuit is a part of the circuit that for some reasons has become “shorter” than it should be. The current in an electrical circuit flows the easiest way and if two points in a circuit with different potentials are connected with low electrical impedance the current is taking a shortcut between the two points.

A simple method for the approximation of short circuit current is the infinite bus short circuit calculation method. This method calculates the worst possible or maximum current that propagates from the transformer in case of a short circuit.

Short Circuit Calculations Using Infinite Bus Method

The motor starting reactance is most often used for short-circuit calculation. However, the resistance to be used for short-circuit calculations is lower than the starting resistance provided on the data sheet. Unless a short-circuit resistance is provided, typical motor X/R ratio curves can be used.

An infinite bus short circuit calculation can be used to determine the maximum short circuit current on the secondary side of a transformer using only transformer nameplate data. This is a good (and simple) method for determining the worst case **MAXIMUM** short circuit current through the transformer since it ignores the source/utility impedance.
